

The AI data centre supply chain

The compute sub-chain as modelled: materials, substrates, packaging, optics, transceivers, racks, operators.

AI SUPPLY CHAIN — COMPUTE SUB-CHAIN
20260730-131249-shock

Visual impact of a Taiwan blockade

TSMC logic, CoWoS packaging, ODM rack integration, OSAT and Micron Taichung HBM: lanes all severed.
Korea HBM, Southeast Asia assembly and the US lanes hold.

AI SUPPLY CHAIN — COMPUTE SUB-CHAIN
20260730-131249-shock

Impact of a six-month Taiwan closure

The model suggests deployed AI compute doesn't move.
Racks already arrive faster than they can be powered, and that standing surplus of undeployed hardware absorbs the closure.

Schematic only, drawn to the argument the modelling establishes; the power line is the run's own ceiling (PUE 1.25; four operators at 0.60 of energisable capacity; power binds below ~0.75 of the pool; if JLL's gigawatts are IT load the ceiling rises 25%). Dock depth is a scenario, not an estimate; the conclusion does not depend on it. Scheduled capacity keeps its published dates; sourced slip evidence (JLL: 57% of projects delayed 3+ months in 2025; Currence: 30 to 50% of the 2026 pipeline slips) pushes relief later than drawn, which widens the gap.

Sources: JLL, 2026 Global Data Center Outlook, Jan 2026: capacity path 12 to 27 GW added per year to 2030, AI share of gigawatts 23% rising to 50%; sets the power line, 372 to 582 racks/wk.

Microsoft on the record: Nadella, BG2 Pod, "chips sitting in inventory that I can't plug in... I don't have warm shells to plug into"; Hood, Q1 FY26 earnings call, "We are, and have been, short now for many quarters" (reported 3 Nov 2025, techzine.eu).

Morgan Stanley, Dec 2025, via WallStreetCN (longbridge.com): 27,300 GB200/GB300 racks shipped in 2025, 70,000 to 80,000 forecast for 2026; the 900/wk drawn sits between expressed operator demand (580) and that forecast.

Amkor IR, 6 Oct 2025 (ir.amkor.com): Peoria, Arizona groundbreaking, first facility in production from early 2028; the dated US packaging step.

Three ways to take this further

01

Your exposure

Seventy metrics sit behind this analysis: sourced, derived and assumed. Only a handful decided the outcome. Your exposure works the same way: when a shock hits your supply chain, a short list of numbers decides what it costs you, whether you know that list or not. We model your chain end to end and find it.

02

The approach

The write-up covers how this was built: the chain as a simulation, seventy graded citations reconciled into one baseline, a backtest against the record before any projection, where AI carried the work and where humans led, and what we learned along the way.

Read it · [Pointing Constellation at the real world](#)

03

AI in your research

AI did much of the work, from research and data gathering through source verification and model building, and the write-up covers how. Useful if you're weighing what AI could do inside your own research process.
